Genito-Urinary System Candidiasis & Candida albicans

The candida

- members of the resident human
- can produce disease ranging from superficial skin or mucous membrane infections to systemic involvement of multiple organs.

The most common opportunistic infections are caused by the yeast Candida albicans

a common inhabitant of the gastrointestinal and genital floras

C. albicans grows in <u>multiple morphologic</u> forms

Nature Reviews | Microbiology

septate hyphae

coenocytic (nonseptate) hyphae

pseudohyphae

The C. albicans <u>cell wall</u> is made up of:

- a mixture of the polysaccharides <u>mannan</u>, <u>glucan</u>, and <u>chitin</u> alone or in complexes with <u>protein</u>.
- The exact <u>composition</u> of the <u>cell wall</u> and surface components <u>varies</u> under different growth and morphologic conditions.

CANDIDIASIS

Candidiasis occurs in localized and disseminated forms.

- Deep tissue and disseminated disease are limited almost exclusively to the immunocompromised.
- Diffuse pneumonia and urinary tract involvement are especially common.

EPIDEMIOLOGY

C. albicans is a common member of the oropharyngeal, gastrointestinal, and female genital flora (30-50% of healthy person).

Infections are endogenous <u>except</u> in cases of direct mucosal contact with <u>lesions in</u> <u>others</u> (eg, through sexual intercourse).

Although C. albicans is a common cause of nosocomial infections, the fungi are also derived more frequently from the patient's own flora.

Invasive procedures and indwelling devices may provide portal of entry,
 the number of Candida may be enhanced by the use of antibacterial agents.

PATHOGENESIS
Because *C. albicans* is regularly present on mucosal surfaces, disease implies a change in the organism, the host, or both.
Shift from yeast to hyphae is associated with enhanced pathogenic potential of *C. albicans*

(invasion).

PATHOGENESIS

C. albicans <u>hyphae</u> have the capacity to form <u>strong attachments</u> to human <u>epithelial cells</u>, mediated by a <u>surface mannoproteins</u>; <u>hyphal</u> <u>wall protein (Hwp1)</u> found only on surface of <u>germ tubes</u> and <u>hyphae</u> & <u>extracellular matrix</u>.

Hyphae

 secrete proteinases and phospholipases that are able to digest epithelial cells and facilitate invasion.

C. albicans has protein surface receptors that bind the C3 component of complement in an antiopsonic manner.

MANIFESTATIONS

Superficial invasion of the m. membranes produces a usually painless, white, cheesy plaque called <u>thrush</u> that is loosely adherent to the mucosal surface.

 MANIFESTATIONS
 Vaginal candidiasis (vulvovaginitis) produces a thick, curd-like discharge and itching of the vulva. Vaginitis may be recurrent.

Chronic mucocutaneous candidiasis is associated with <u>specific T-cell defects</u>.

Inflammatory patches similar to thrush may develop in the <u>esophagus</u> and <u>intestine</u> with or without associated oral candidiasis.

 Painful swallowing and substernal chest pain are the most common symptoms

Urinary tract infections are ascending or <u>hematogenous</u> may produce cystitis, pyelonephritis, abscesses, or expanding fungus ball lesions in the renal pelvis.

Endophthalmitis appears as white cotton on the retina. Endophthalmitis and infections of other eye structures can lead to <u>blindness</u>.

DIAGNOSIS

- KOH and Gram smears of <u>superficial</u> lesions show budding yeast and hyphae.
- Cultures from specimens such as sputum run the risk of contamination from the normal <u>flor</u>a or a superficial mucous membrane lesion.
- Lung involvement requires a direct <u>aspirate</u>, <u>biopsy</u>, or bronchoalveolar <u>lavage</u>.

DIAGNOSIS

- Deep organ involvement is difficult to prove without a <u>direct aspirate</u> or <u>biopsy</u>.
- Immunodiagnostic procedures are not routine.

TREATMENT

C. albicans is usually <u>susceptible</u> to:

nystatin, amphotericin B, flucytosine, and the azoles.

Topical nystatin or azoles generally used for the treatment of <u>superficial lesions</u>.

TREATMENT

Deeper infections may resolve <u>spontaneously</u> with <u>elimination</u> or <u>control</u> of predisposing conditions, as an <u>infected catheter</u> or control of <u>diabetes</u>.

 Amphotericin B, flucytosine, and azoles for invasive disease
